In the article titled „Assessing the Security of Using LLMs For Coding" the author provides us with data comparing vulnerabilities in code generated in different programming languages with different AI models. Since 2023 the mean security pass rate improved by only one percent point (right now at 56.3%). That means around 40% of all generated code contains a known, serious, and easily detectable vulnerability. According to the article the safest model is GPT-5.5 at 68% pass rate, while the lowest scoring out of mainstream models is DeepSeek V4 – Flash at 51%. What's worth noting, is that every accounted model had a 100% syntax pass rate except Claude-Opus 4.8 at 99%. The easiest language for LLMs to write a secure code is Python, which remained at 62.5% throughout the years. The least secure language, however the only with a steady incline is Java, for which security pass rate improved by 8 percent points since 2023. The author suggests we may not see a future where vibe-coding is relevant; AI is simply not improving.
